Acknowledgement

First and foremost, I am heartily thankful to my supervisor of this work, Dr. Kamarul Hawari bin Ghazali, whose encouragement, guidance and advice from the initial to the final level throughout the course of my graduate studies. He inspired me greatly to work in this project. This work would not be possible without his willingness to motivate me contributed tremendously to my work.

Besides, I wish to express my gratitude to the authority of Faculty of Electrical and Electronic for providing me with the good environment and facilities to complete this work. I would like to extend my gratitude to those who gave me the possibilities for me to complete this work especially my beloved parents and my siblings for giving such a great motivation and financial support.

Finally, an honourable mention goes to my graduate friends especially to those group members under Dr. Kamarul supervision whose sharing all the literature and skills. Special thanks to the administrator who help me to find the research material easily.

Abstract

Nowadays, from time to time technologies become more advances that bring much advantage for our human life. But, it needs time for us to learn especially the knowledge about image processing because it uses for many field such as medical or aerospace. So, this project is a study that mains in the basic applications of image processing. It will introduce to the new learner about the image processing. MATLAB software is the main tools that will be use for the application of image processing. MATLAB software has been chosen because of this tool is a universal and all well known tool. Then, MATLAB GUI is one of the parts that use to create the module of those applications. The main outcome of this project is to create a module about the application of image processing for learning purpose. In this module which will cover two parts, which is shape detection and color recognition (RGB). The method that will be use for the shape detection is edge detection. A few edge-finding methods will be used for this application such as Sobel, Prewitt, Roberts, Laplacian of Gaussian (Log), zero-cross and also canny technique. Therefore, the user can learn much in this module. Then, for the application of color part used histogram to recognize the 3 basic colors, that are red, green and blue. To complete this project it need to further study about the MATLAB tools briefly and also all the technique that use to create that module. Finally, this module can give the benefit for the new learner of image processing to more understand about the useful applications. This module was designed to perform basic applications effectively.

Abstrak

Pada masa kini, kemajuan teknologi dari semasa ke semasa telah membawa banyak manfaat dalam kehidupan harian manusia. Tapi, ia memerlukan masa bagi kita untuk belajar terutama pengetahuan tentang pemprosesan imej kerana kegunaannya dalam pelbagai bidang yang amat meluas seperti perubatan atau aerospace. Jadi, projek ini merupakan kajian yang berkaitan dengan aplikasi pemprosesan imej. Ini akan memperkenalkan kepada mereka yang baru belajar tentang pemprosesan imej. MATLAB adalah alat utama yang akan digunakan untuk aplikasi pemprosesan imej. MATLAB telah dipilih kerana alat ini adalah universal dan semua amat mengenalinya dalam bidang kejuruteraan ini. Kemudian, MATLAB GUI merupakan salah satu bahagian yang digunakan untuk membuat modul dari aplikasi tersebut. Objektif utama dari projek ini adalah menghasilkan modul tentang aplikasi pemprosesan imej untuk tujuan belajar. Dalam modul ini akan merangkumi dua bahagian, iaitu pengenalanpastian bentuk dan warna (RGB). Kaedah yang akan digunakan untuk pengesanan bentuk adalah pengesanan tepi. Teknik ini merangkumi beberapa kaedah yang akan digunakan untuk aplikasi seperti teknik Sobel, Prewitt, Roberts, Laplacian dari Gaussian (Log), zero-cross dan juga canny. Oleh kerana itu, pengguna boleh banyak belajar di dalam modul ini. Maka, untuk aplikasi bahagian warna yang digunakan adalah histogram untuk mengenali 3 warna iaitu merah, hijau dan biru. Demi menyiapkan projek ini perlu mempelajari lebih lanjut mengenai alat MATLAB terlebih dahulu dan juga semua teknik yang digunakan untuk membuat modul itu. Akhirnya, modul ini dapat memberikan manfaat bagi mereka baru ingin belajar pemprosesan imej untuk lebih memahami tentang aplikasi bermanfaat yang ada. Modul ini direka dengan tujuan mampu menonjolkan aplikasi asas dengan berkesan.

CHAPTER 1

INTRODUCTION

New technologies need to be exploring for the development a system for help in the human daily life. Exploring and learn a new technologies is not that easy because it need some guide for it. Nowadays, the application of image processing and analysis are now used in a wide range of industrial, artistic, and educational applications such as biotechnology, medicine, environmental science and art. Image processing in biotechnology or medicine also need use the basic application of object detection and color recognition. So, development of object detection and color recognition module need the intelligence on new technologies as a contribution due to help the industries and also education field. Designing this module is useful for the new learner and this module is a process to determine the shape detection and color recognition. In this module will be cover several method such as edge detection and using histogram. The basic tools that be used is MATLAB software. That is basic software that used in engineering field especially. Then implement MATLAB GUI which is one of the functions in MATLAB to design as simple module applications. Therefore, the new learner can follow step by step in this module to know more about the application of image processing that helpful in the entire field.

1.1 Problem Statement

Exploring a new technology like image processing is quite hard and need some guide for it. In the internet got a lot of the manual guide for it but it hard for new learner to really understand about it. Unfortunately, the guide from a module or system that can let the new learner to try it out some method that can be use for the image processing applications is much effective. So, a module about that is needed then this project is important to complete for that purpose.

1.2 Objective

This project aims to create a module about the application of image processing which using the MATLAB software as the main tools and use the application Graphics User Integrated (GUI) skill. In these modules which cover two parts, shape detection (circle and square) and color recognitions (RGB). Both of these basic applications are suitable for the new learner for their understanding to help in their learning process so, that is the main purpose of create this module.

1.3 Scope of project

The related scopes of this project are basic application of image processing and MATLAB software. It involves data collection, image acquisition, image processing,

classification and decision. The data collection involves collecting the image consists of different shape or color. Image processing consist of shape detection and color recognition that can be many type of techniques but we used edge detection and histogram for the two applications.

MATLAB Software is utilized where .m file as the location to write program and form linkages between main program and sub programs, also, as the platform where ANN program is trained to be accurate, efficient and user friendly.

1.3 Thesis Outline

This thesis is organized as below:

Chapter 1 will describes the introduction of this system, the purpose of this project, problem statement, the work scope and brief explanation of this project.

In **Chapter 2**, the reviews about the information find on all the material or data used include the software in the development of this project will be shown.

Chapter 3 will explain about all the methods use in development of this system and also step by step on develop the module for training purpose and lastly described about the execution part.

Chapter 4 will show all the results followed by the explanation and discussion about the results from the beginning step until the end of development module.

Last chapter of **Chapter 5** will have a summary to describe the overall part of this project and come up with some recommendations and improvement.

Chapter 2

LITERATURE REVIEW

This chapter will review on the information gathered in developing the simple system or module for object detection and color recognition. The information is the entire basic introduction to develop that system for learning purpose including the basic knowledge about the image processing, creating standalone file and also interfacing MATLAB with GUI.

2.1 Image processing

Image processing is the analysis of a picture using techniques that can identify shades, color and relationships that cannot be perceived by the human eye. Image processing is used to solve identification problems, such as in forensic medicine or in creating weather maps from satellite pictures. [1] It deals with images in bitmapped graphics format that have been scanned in or captured with digital cameras.

Image processing typically attempts to accomplish into three parts that is restoring images, enhancing images and understanding images. Restoration process takes a corrupted image and attempts to recreate a clean original image which removing sensor noise and restoring old, archived film and images. [1]

Figure 2.1: Example of restoration image

Enhancement process alters an image to make its meaning clearer to human observers which often user used to increase the contrast in images that are overly dark or light.

Figure 2.2: Example of enhancement image

Understanding process usually attempts to mimic the human visual system in extracting meaning from an image which includes many different tasks like segmentation, classification and interpretation. The process begin by identifying object in an image, then assigns labels to individual pixels and extract some meaning from the image as a whole.

Figure 2.3: Example of understanding images

2.1.1 Threshold image

In many vision applications, it is useful to be able to separate out the regions of the image corresponding to objects in which we are interested, from the regions of the image that correspond to background. Thresholding often provides an easy and convenient way to perform this segmentation on the basis of the different intensities or colors in the foreground and background regions of an image.

Threshold converts each pixel into black, white or unchanged depending on whether the original color value is within the threshold range. Threshold is a very important command that is often used to prepare scanned RGB or RGBa images for vectorization or use as guide layers in the creation of drawings. It can be used with raster data images to set off ranges of values that may then be used for subsequent analysis or as selection masks. [4]

In addition, it is often useful to be able to see what areas of an image consist of pixels whose values lie within a specified range, or *band* of intensities (or colors). Thresholding can be used for this as well. Thresholding is the simplest method of image segmentation. From a grayscale image, thresholding can be used to create binary images.

The input to a thresholding operation is typically a grayscale or color image. In the simplest implementation, the output is a binary image representing the segmentation. Black pixels correspond to background and white pixels correspond to foreground (or *vice versa*). In simple implementations, the segmentation is determined by a single parameter known as the intensity threshold. In a single pass, each pixel in the image is compared with this threshold. If the pixel's intensity is higher than the threshold, the

pixel is set to, say, white in the output. If it is less than the threshold, it is set to black.
[4]

Figure 2.4: Original image

Figure 2.5: RGB to gray scale

Figure 2.6: Threshold to binary image

Figure 2.7: Inverse binary image

In more sophisticated implementations, multiple thresholds can be specified, so that a *band* of intensity values can be set to white while everything else is set to black. For color or multi-spectral images, it may be possible to set different thresholds for each color channel, and so select just those pixels within specified cuboids in RGB space. Another common variant is to set to black all those pixels corresponding to background,

but leave foreground pixels at their original color/intensity (as opposed to forcing them to white), so that that information is not lost.

There are categorizing the thresholding methods in six groups:

1. Histogram shape-based methods, where, for example, the peaks, valleys and curvatures of the smoothed histogram are analyzed.
2. Clustering-based methods, where the gray-level samples are clustered in two parts as background and foreground ~object! Or alternately are modeled as a mixture of two Gaussians.
3. Entropy-based methods result in algorithms that use the entropy of the foreground and background regions, the cross-entropy between the original and binaries image, etc.
4. Object attribute-based methods search a measure of similarity between the gray-level and the binaries images, such as fuzzy shape similarity, edge coincidence, etc.
5. The spatial methods use higher-order probability distribution and/or correlation between pixels
6. Local methods adapt the threshold value on each pixel to the local image characteristics.

2.1.2 Edge Detection

Edge detection is a fundamental tool used in most image processing applications to obtain information from the frames as a precursor step to feature extraction and object segmentation. This process detects outlines of an object and boundaries between objects and the background in the image. An edge-detection filter can also be used to improve the appearance of blurred or anti-aliased video streams.

The basic edge-detection operator is a matrix area gradient operation that determines the level of variance between different pixels. The edge-detection operator is calculated by forming a matrix centered on a pixel chosen as the center of the matrix area. If the value of this matrix area is above a given threshold, then the middle pixel is classified as an edge. [6]

Among the gradient-based detectors are Sobel, Prewitt, and Roberts. By default, edge uses the Sobel method to detect edges but the following provides a complete list of all the edge-finding methods supported by this function [6]:

- The Sobel method finds edges using the Sobel approximation to the derivative. It returns edges at those points where the gradient of I is maximum.
- The Prewitt method finds edges using the Prewitt approximation to the derivative. It returns edges at those points where the gradient of I is maximum.
- The Roberts method finds edges using the Roberts approximation to the derivative. It returns edges at those points where the gradient of I is maximum.
- The Laplacian of Gaussian method finds edges by looking for zero crossings after filtering I with a Laplacian of Gaussian filter.
- The zero-cross method finds edges by looking for zero crossings after filtering I with a filter you specify.

- The Canny method finds edges by looking for local maxima of the gradient of I . The gradient is calculated using the derivative of a Gaussian filter. The method uses two thresholds, to detect strong and weak edges, and includes the weak edges in the output only if they are connected to strong edges. This method is therefore less likely than the others to be fooled by noise, and more likely to detect true weak edges.

The Prewitt operator measures two components. The vertical edge component is calculated with kernel K_x and the horizontal edge component is calculated with kernel K_y . $|K_x| + |K_y|$ gives an indication of the intensity of the gradient in the current pixel.

$K_x =$			$K_y =$		
-1	0	1	1	1	1
-1	0	1	0	0	0
-1	0	1	-1	-1	-1

Figure 2.8: Prewitt horizontal and vertical operators

Depending on the noise characteristics of the image or streaming video, edge detection results can vary. Gradient-based algorithms such as the Prewitt filter have a major drawback of being very sensitive to noise. The size of the kernel filter and coefficients are fixed and cannot be adapted to a given image. An adaptive edge-detection algorithm is necessary to provide a robust solution that is adaptable to the varying noise levels of these images to help distinguish valid image content from visual artifacts introduced by noise.
